

ABSTRACT OF THE DISCLOSURE

A photo print is produced from image data. A system controller classifies the photo prints on the basis of additional information of the image data under a classification condition recorded in a smart medium. The photo prints are discharged to sorting trays. The system controller allocates the respective sorting trays to each classification. When the photo print is discharged to the sorting tray, a sorter switches a conveyance route of the photo print in response to a classification signal sent from the system controller. The photo prints are distributed to the sorting trays every classification. Owing to this, the photo prints are prevented from being discharged in a mixed state.
